**Computer Graphics  
CMU 15-462/662**

# Last Time: Linear Algebra

## ■ Touched on a variety of topics:

vectors & vector spaces  
 norm  
 $L^2$  norm/inner product  
 span  
 Gram-Schmidt  
 linear systems  
 quadratic forms  
 ...

vectors as functions  
 inner product  
 linear maps  
 basis  
 frequency decomposition  
 bilinear forms  
 matrices  
 ...

## ■ Don't have time to cover everything!

## ■ But there are some fantastic lectures online:

3Blue1Brown — Essence of Linear Algebra

Robert Ghrist — Calculus Blue

...

(Let us know about others online!)

# Vector Calculus in Computer Graphics

- Today's topic: **vector calculus**.
- Why is vector calculus important for computer graphics?
  - Basic language for talking about spatial relationships, transformations, etc.
  - Much of modern graphics (physically-based animation, geometry processing, etc.) formulated in terms of *partial differential equations* (PDEs) that use div, curl, Laplacian...
  - As we saw last time, vector-valued data is everywhere in graphics!

# Euclidean Norm

- Last time, developed idea of *norm*, which measures total size, length, volume, intensity, etc.
- For geometric calculations, the norm we most often care about is the **Euclidean norm**
- Euclidean norm is any notion of length preserved by rotations/translations/reflections of space.
- In *orthonormal* coordinates:

$$|\mathbf{u}| := \sqrt{u_1^2 + \dots + u_n^2}$$

Not true for all norms!  
(Can you think of an example?)

**WARNING:** This quantity does *not* encode geometric length unless vectors are encoded in an orthonormal basis. (Common source of bugs!)

# Euclidean Inner Product / Dot Product

- Likewise, lots of possible inner products—intuitively, measure some notion of “alignment.”
- For *geometric* calculations, want to use inner product that captures something about geometry!
- For n-dimensional vectors, **Euclidean inner product** defined as

$$\langle \mathbf{u}, \mathbf{v} \rangle := |\mathbf{u}| |\mathbf{v}| \cos(\theta)$$

- In orthonormal Cartesian coordinates, can be represented via the **dot product**

$$\mathbf{u} \cdot \mathbf{v} := u_1 v_1 + \cdots + u_n v_n$$

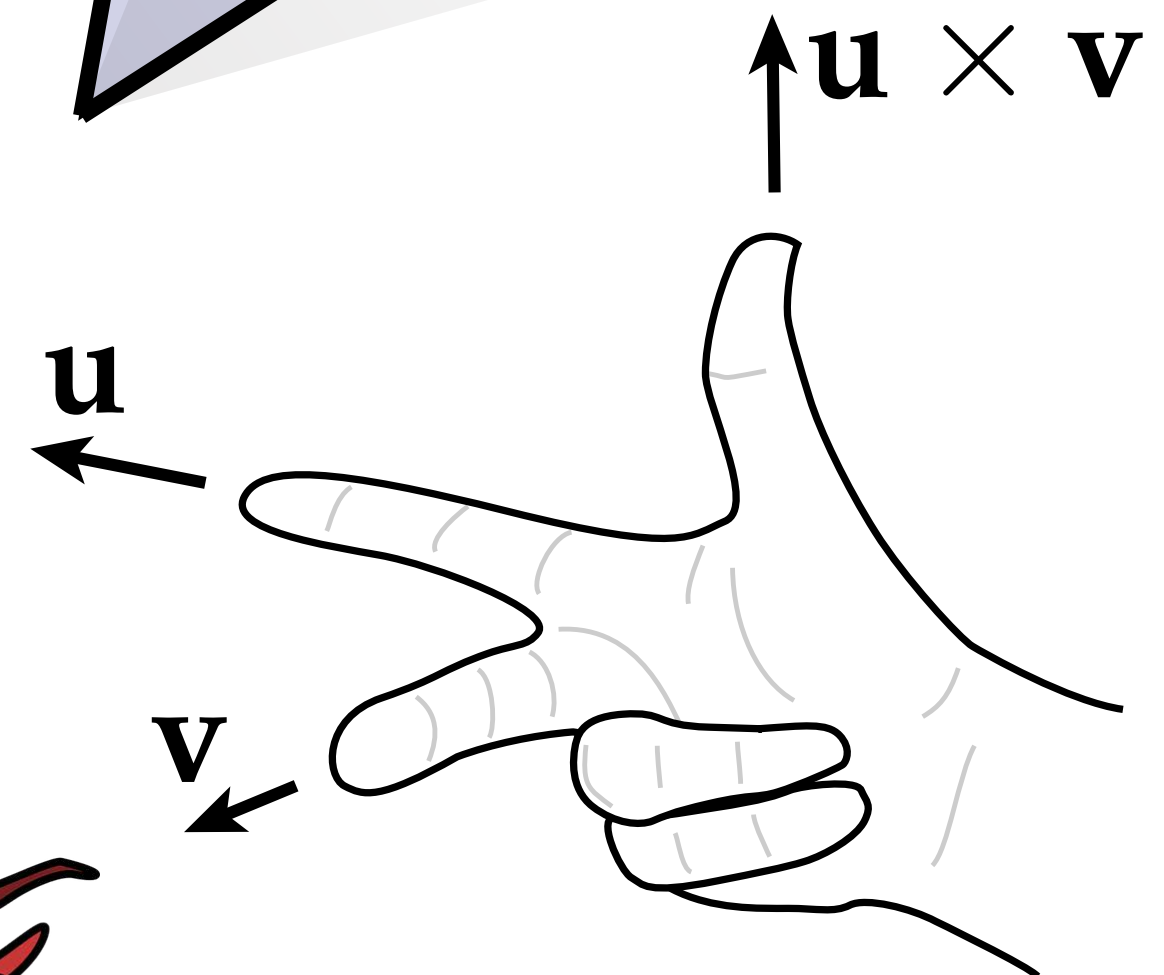

- **WARNING:** As with Euclidean norm, no geometric meaning unless coordinates come from an orthonormal basis.

# Cross Product

- Inner product takes two vectors and produces a *scalar*
- In 3D, **cross product** is a natural way to take two vectors and get a *vector*, written as “ $u \times v$ ”
- Geometrically:
  - magnitude equal to parallelogram area
  - direction orthogonal to both vectors
  - ...but which way?
- Use “right hand rule”

SMH...

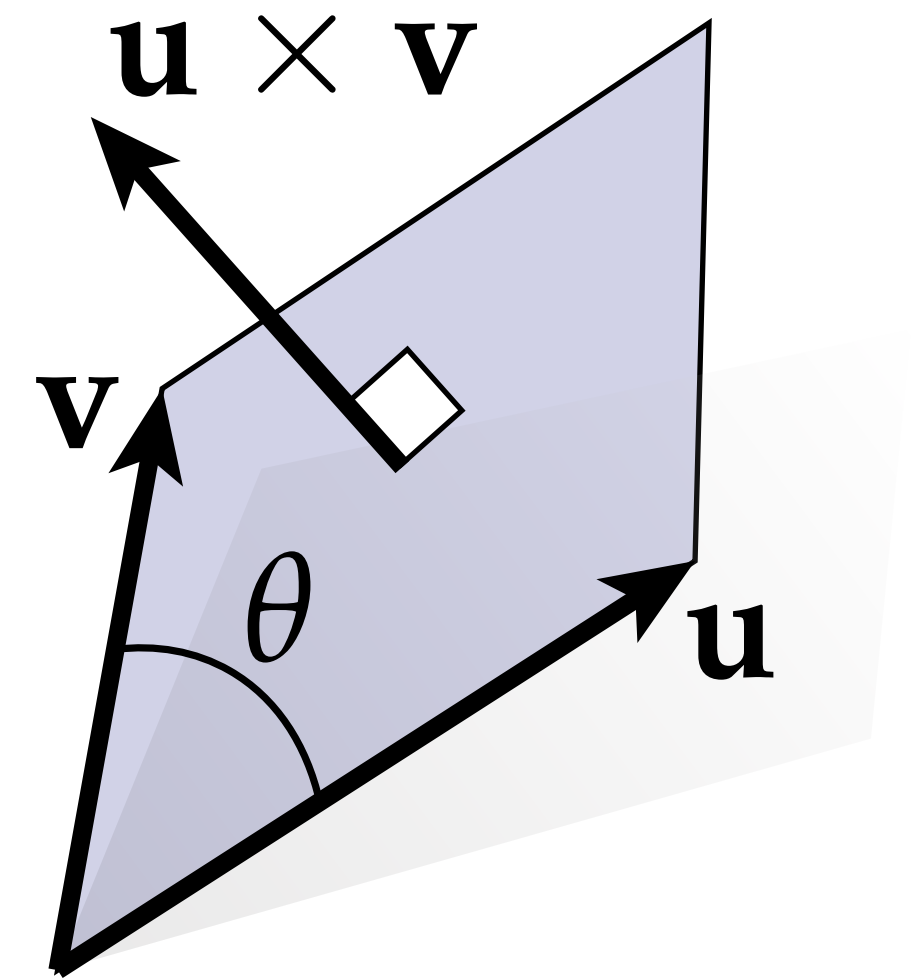

(Q: Why only 3D?)

# Cross Product, Determinant, and Angle

- More precise definition (that does not require hands):

$$\sqrt{\det(\mathbf{u}, \mathbf{v}, \mathbf{u} \times \mathbf{v})} = \|\mathbf{u}\| \|\mathbf{v}\| \sin(\theta)$$

- $\theta$  is angle between  $\mathbf{u}$  and  $\mathbf{v}$
- “det” is determinant of three column vectors
- Uniquely determines coordinate formula:

$$\mathbf{u} \times \mathbf{v} := \begin{bmatrix} u_2 v_3 - u_3 v_2 \\ u_3 v_1 - u_1 v_3 \\ u_1 v_2 - u_2 v_1 \end{bmatrix}$$

$$\begin{vmatrix} \mathbf{e}_1 & \mathbf{e}_2 & \mathbf{e}_3 \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}$$

(mnemonic)

- Useful abuse of notation in 2D:  $\mathbf{u} \times \mathbf{v} := u_1 v_2 - u_2 v_1$

# Cross Product as Quarter Rotation

- Simple but useful observation for manipulating vectors in 3D: cross product with a unit vector  $N$  is equivalent to a quarter-rotation in the plane with normal  $N$ :

- Q: What is  $N \times (N \times u)$ ?
- Q: If you have  $u$  and  $N \times u$ , how do you get a rotation by some arbitrary angle  $\theta$ ?

# Matrix Representation of Dot Product

- Often convenient to express dot product via matrix product:

$$\mathbf{u} \cdot \mathbf{v} = \mathbf{u}^T \mathbf{v} = \begin{bmatrix} u_1 & \cdots & u_n \end{bmatrix} \begin{bmatrix} v_1 \\ \vdots \\ v_n \end{bmatrix} = \sum_{i=1}^n u_i v_i$$

- By the way, what about some other inner product?

- E.g.,  $\langle \mathbf{u}, \mathbf{v} \rangle := 2u_1v_1 + u_1v_2 + u_2v_1 + 3u_2v_2$

$$\underbrace{\begin{bmatrix} u_1 & u_2 \end{bmatrix}}_{\mathbf{u}^T} \underbrace{\begin{bmatrix} 2 & 1 \\ 1 & 3 \end{bmatrix}}_{\mathbf{A}} \underbrace{\begin{bmatrix} v_1 \\ v_2 \end{bmatrix}}_{\mathbf{v}} = \begin{bmatrix} u_1 & u_2 \end{bmatrix} \begin{bmatrix} 2v_1 + v_2 \\ v_1 + 3v_2 \end{bmatrix}$$

$$= (2u_1v_1 + u_1v_2) + (u_2v_1 + 3u_2v_2). \quad \checkmark$$

**Q: Why is matrix representing inner product always *symmetric* ( $\mathbf{A}^T = \mathbf{A}$ )?**

# Matrix Representation of Cross Product

- Can also represent cross product via matrix multiplication:

$$\mathbf{u} := (u_1, u_2, u_3) \quad \Rightarrow \quad \hat{\mathbf{u}} := \begin{bmatrix} 0 & -u_3 & u_2 \\ u_3 & 0 & -u_1 \\ -u_2 & u_1 & 0 \end{bmatrix}$$

$$\mathbf{u} \times \mathbf{v} = \hat{\mathbf{u}}\mathbf{v} = \begin{bmatrix} 0 & -u_3 & u_2 \\ u_3 & 0 & -u_1 \\ -u_2 & u_1 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} \quad \text{(Did we get it right?)}$$

- Q: Without building a new matrix, how can we express  $\mathbf{v} \times \mathbf{u}$ ?
- A: Useful to notice that  $\mathbf{v} \times \mathbf{u} = -\mathbf{u} \times \mathbf{v}$  (why?). Hence,

$$\mathbf{v} \times \mathbf{u} = -\hat{\mathbf{u}}\mathbf{v} = \hat{\mathbf{u}}^T \mathbf{v}$$

# Determinant

- Q: How do you compute the **determinant** of a matrix?

$$\mathbf{A} := \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

- A: Apply some algorithm somebody told me once upon a time:

$$\begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix} \quad \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix} \quad \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

$$\det(\mathbf{A}) = a(ei - fh) + b(fg - di) + c(dh - eg)$$

Totally obvious... right?

- Q: No! What the heck does this number *mean*?!?

# Determinant, Volume and Triple Product

- Better answer:  $\det(\mathbf{u}, \mathbf{v}, \mathbf{w})$  encodes (signed) volume of parallelepiped with edge vectors  $\mathbf{u}, \mathbf{v}, \mathbf{w}$ .

$$\det(\mathbf{u}, \mathbf{v}, \mathbf{w}) = (\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = (\mathbf{v} \times \mathbf{w}) \cdot \mathbf{u} = (\mathbf{w} \times \mathbf{u}) \cdot \mathbf{v}$$

- Relationship known as a “triple product formula”
- (Q: What happens if we reverse order of cross product?)

# Determinant of a Linear Map

- Q: If a matrix  $A$  encodes a *linear map*  $f$ , what does  $\det(A)$  mean?

**(First: need to recall how a matrix encodes a linear map!)**

# Representing Linear Maps via Matrices

- Key example: suppose I have a linear map

$$f(\mathbf{u}) = u_1 \mathbf{a}_1 + u_2 \mathbf{a}_2 + u_3 \mathbf{a}_3$$

- How do I encode as a matrix?

- Easy: “a” vectors become matrix columns:

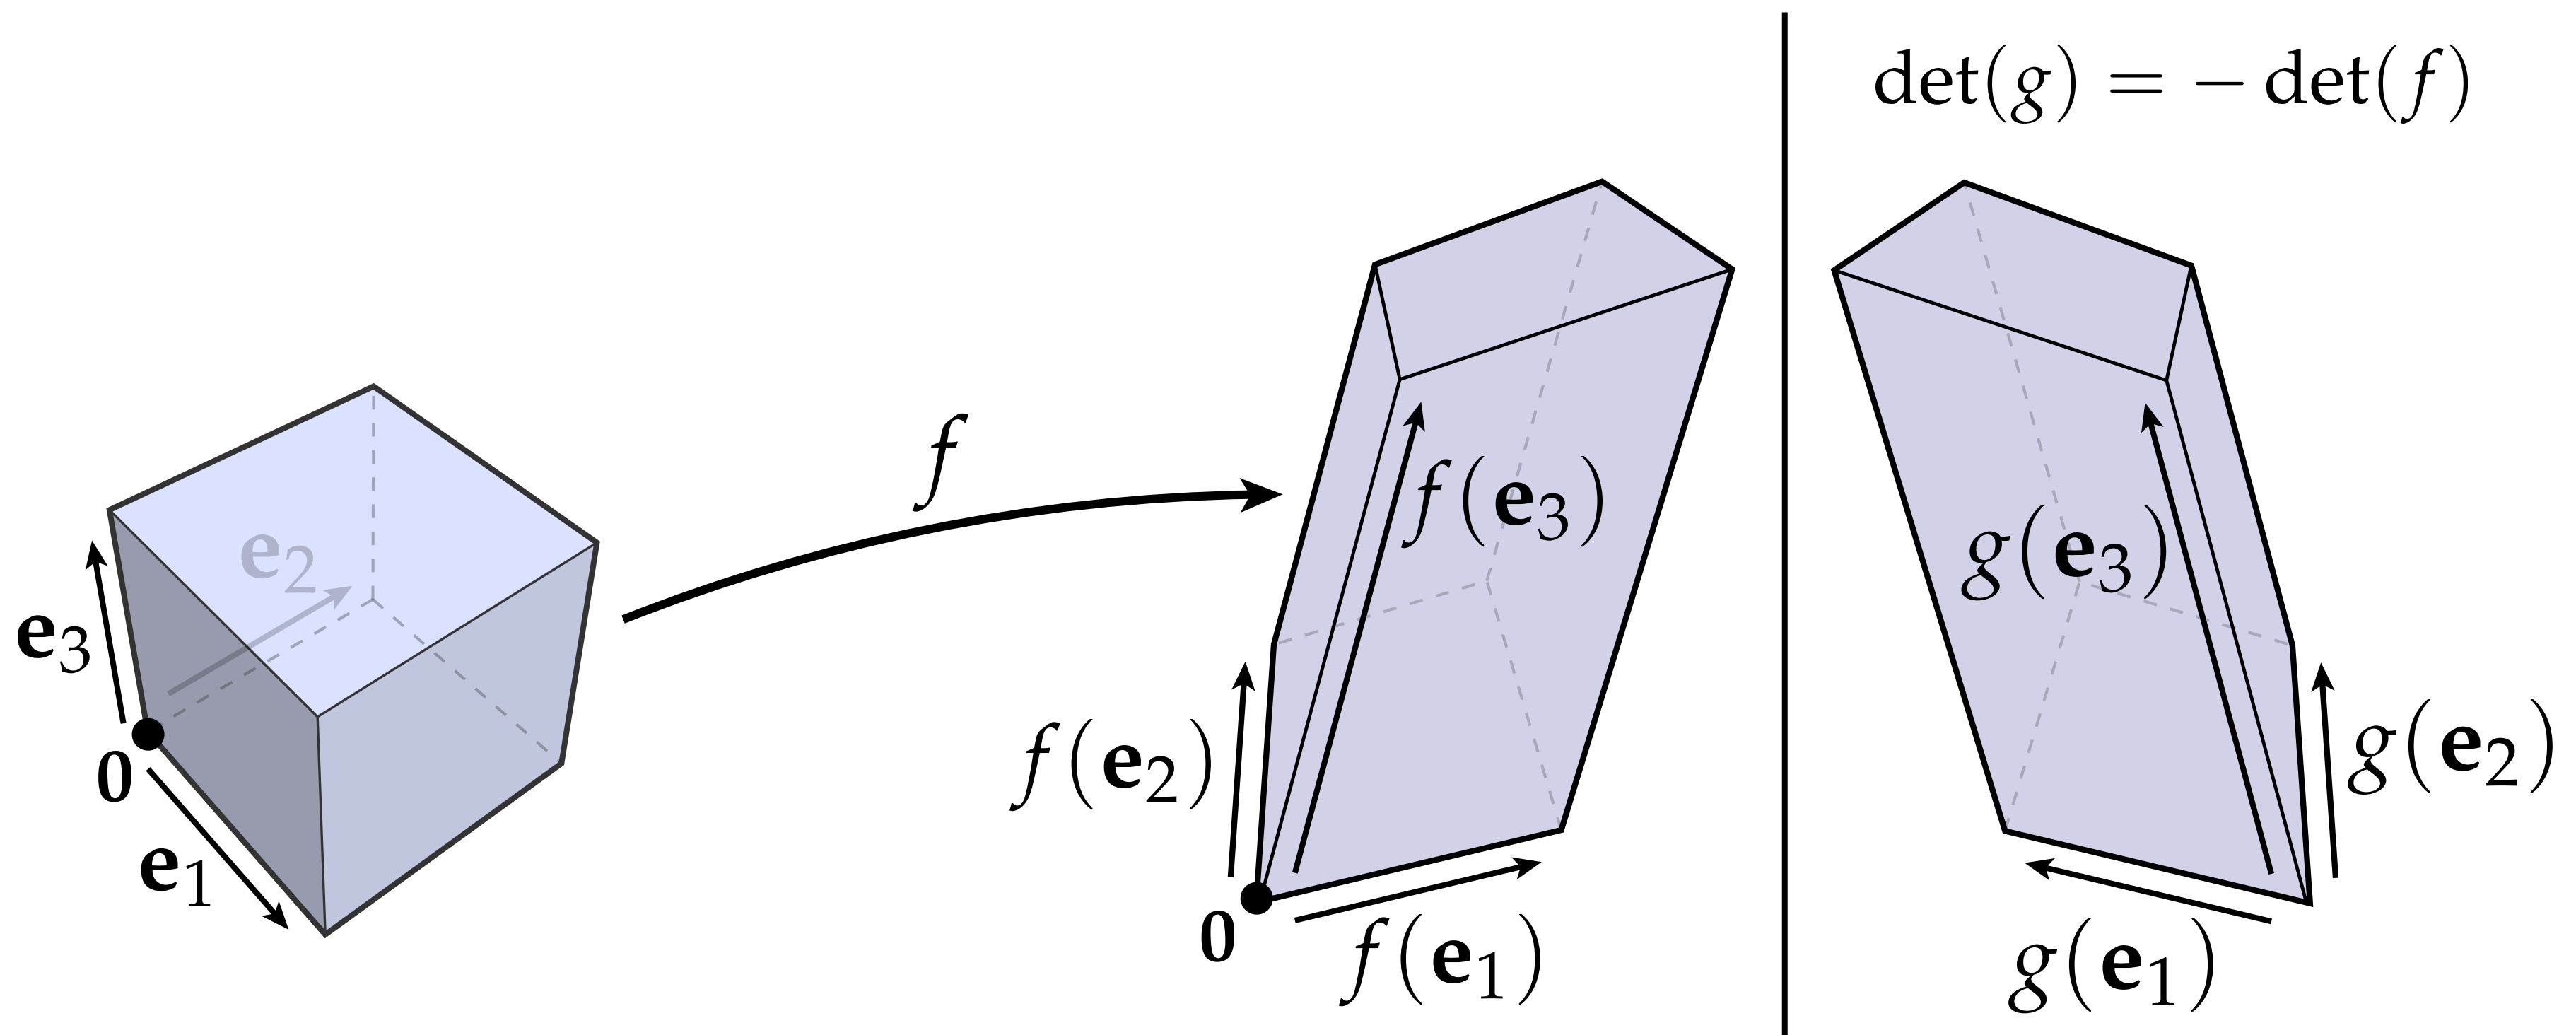

$$A := \begin{bmatrix} | & | & | \\ \mathbf{a}_1 & \mathbf{a}_2 & \mathbf{a}_3 \\ | & | & | \end{bmatrix} = \begin{bmatrix} a_{1,x} & a_{2,x} & a_{3,x} \\ a_{1,y} & a_{2,y} & a_{3,y} \\ a_{1,z} & a_{2,z} & a_{3,z} \end{bmatrix}$$

- Now, matrix-vector multiply recovers original map:

$$A \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \begin{bmatrix} a_{1,x}u_1 + a_{2,x}u_2 + a_{3,x}u_3 \\ a_{1,y}u_1 + a_{2,y}u_2 + a_{3,y}u_3 \\ a_{1,z}u_1 + a_{2,z}u_2 + a_{3,z}u_3 \end{bmatrix} = u_1 \mathbf{a}_1 + u_2 \mathbf{a}_2 + u_3 \mathbf{a}_3$$

# Determinant of a Linear Map

- Q: If a matrix  $A$  encodes a *linear map*  $f$ , what does  $\det(A)$  mean?

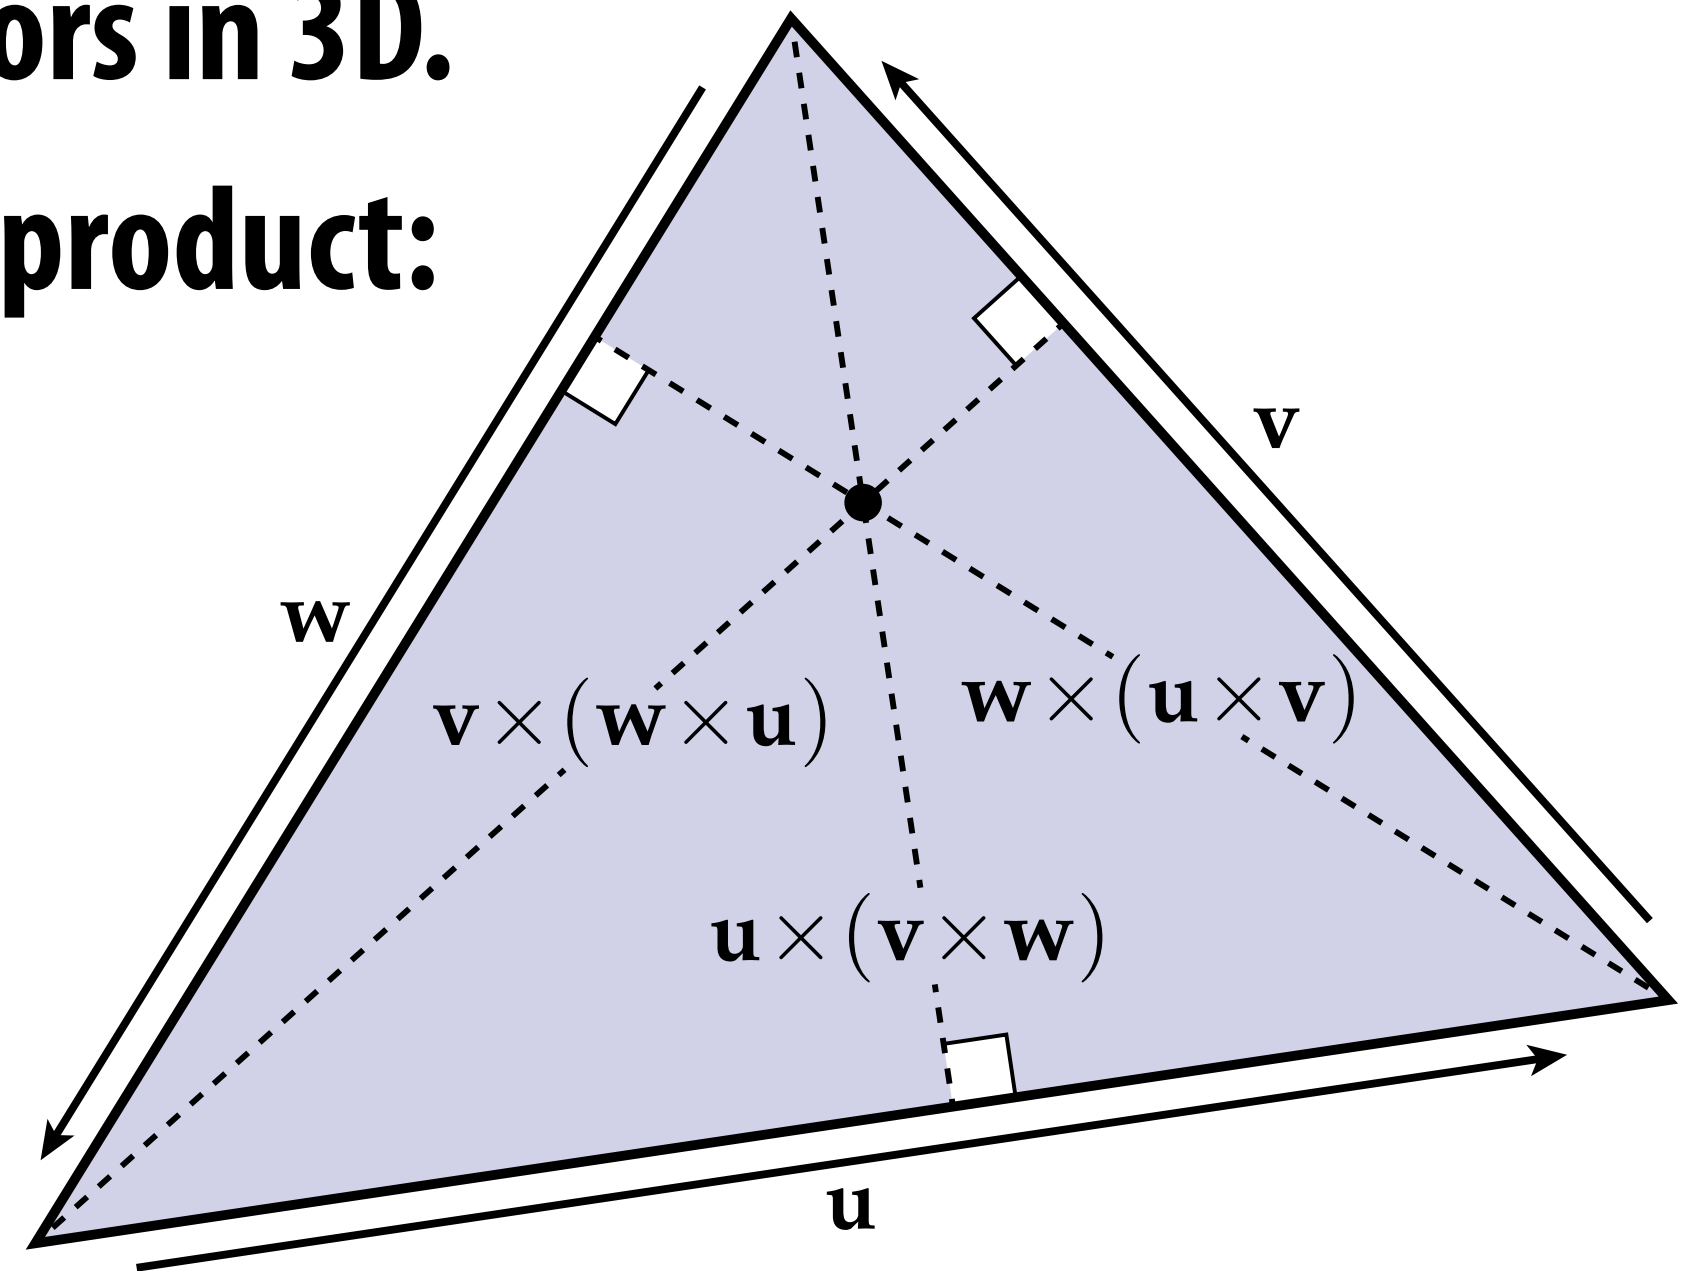

- A: It measures the *change in volume*.
- Q: What does the *sign* of the determinant tell us, in this case?
- A: It tells us whether *orientation* was reversed ( $\det(A) < 0$ )

(Do we really need a *matrix* in order to talk about the determinant of a linear map?)

# Other Triple Products

- Super useful for working w/ vectors in 3D.
- E.g., **Jacobi identity** for the cross product:

$$\begin{aligned} \mathbf{u} \times (\mathbf{v} \times \mathbf{w}) &+ \\ \mathbf{v} \times (\mathbf{w} \times \mathbf{u}) &+ \\ \mathbf{w} \times (\mathbf{u} \times \mathbf{v}) &= 0 \end{aligned}$$

- Why is it true, geometrically?
- There *is* a geometric reason, but **not nearly as obvious** as det: has to do w/ fact that triangle's altitudes meet at a point.
- Yet another triple product: **Lagrange's identity**

$$\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = \mathbf{v}(\mathbf{u} \cdot \mathbf{w}) - \mathbf{w}(\mathbf{u} \cdot \mathbf{v})$$

(Can you come up with a geometric interpretation?)

# Differential Operators - Overview

- Next up: **differential operators** and **vector fields**.
- Why is this useful for computer graphics?
  - Many physical/geometric problems expressed in terms of *relative rates of change* (ODEs, PDEs).
  - These tools also provide foundation for numerical optimization—e.g., minimize cost by following the *gradient* of some objective.

# Derivative as Slope

- Consider a function  $f(x): \mathbb{R} \rightarrow \mathbb{R}$
- What does its derivative  $f'$  mean?
- One interpretation “rise over run”
- Corresponds to standard definition:

$$f'(x_0) := \lim_{\varepsilon \rightarrow 0} \frac{f(x_0 + \varepsilon) - f(x_0)}{\varepsilon}$$

- Careful! What if slope is different when we walk in opposite direction?

$$f^+(x_0) := \lim_{\varepsilon \rightarrow 0} \frac{f(x_0 + \varepsilon) - f(x_0)}{\varepsilon}$$

$$f^-(x_0) := \lim_{\varepsilon \rightarrow 0} \frac{f(x_0) - f(x_0 - \varepsilon)}{\varepsilon}$$

- **Differentiable** at  $x_0$  if  $f^+ = f^-$ .

**Many functions in graphics are NOT differentiable!**

# Derivative as Best Linear Approximation

- Any smooth function  $f(x)$  can be expressed as a *Taylor series*:

$$f(x) = \overset{\text{constant}}{f(x_0)} + \overset{\text{linear}}{f'(x_0)(x - x_0)} + \overset{\text{quadratic}}{\frac{(x - x_0)^2}{2!} f''(x_0)} + \dots$$

- Replacing complicated functions with a linear (and sometimes quadratic) approximation is a powerful trick in graphics algorithms—we'll see many examples.

# Derivative as Best Linear Approximation

- Intuitively, same idea applies for functions of multiple variables:

**How do we think about derivatives for a function that has multiple variables?**

# Directional Derivative

- One way: suppose we have a function  $f(x_1, x_2)$ 
  - Take a “slice” through the function along some line
  - Then just apply the usual derivative!
  - Called the **directional derivative**

# Gradient

- Given a multivariable function  $f(\mathbf{x})$ , **gradient**  $\nabla f(\mathbf{x})$  assigns a vector at each point:

“nabla”

$f(\mathbf{x})$

$\nabla f(\mathbf{x})$

- (Ok, but which vectors, exactly?)

# Gradient in Coordinates

- **Most familiar definition: list of *partial derivatives***
- **I.e., imagine that all but one of the coordinates are just constant values, and take the usual derivative**

$$\nabla f = \begin{bmatrix} \partial f / \partial x_1 \\ \vdots \\ \partial f / \partial x_n \end{bmatrix}$$

- **Two potential problems:**
  - **Role of inner product is not clear (more later!)**
  - **No way to differentiate *functions of functions*  $F(f)$  since we don't have a finite list of coordinates  $x_1, \dots, x_n$**
- **Still, extremely common way to calculate the gradient...**

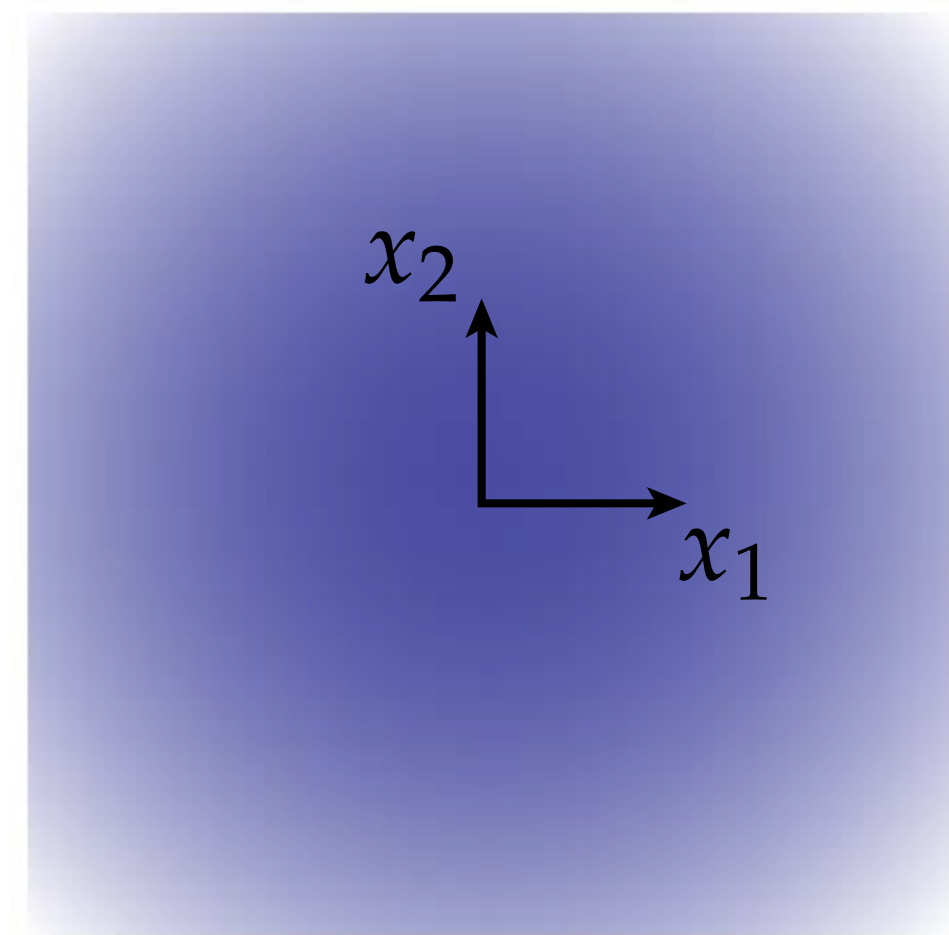

# Example: Gradient in Coordinates

$$f(\mathbf{x}) := x_1^2 + x_2^2$$

$$\frac{\partial f}{\partial x_1} = \frac{\partial}{\partial x_1} x_1^2 + \frac{\partial}{\partial x_1} x_2^2 = 2x_1 + 0$$

$$\frac{\partial f}{\partial x_2} = \frac{\partial}{\partial x_2} x_1^2 + \frac{\partial}{\partial x_2} x_2^2 = 0 + 2x_2$$

$$\nabla f(\mathbf{x}) = \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} = 2\mathbf{x}$$

$f(\mathbf{x})$

$\nabla f(\mathbf{x})$

# Gradient as Best Linear Approximation

Another way to think about it: at each point  $\mathbf{x}_0$ , gradient is the vector  $\nabla f(\mathbf{x}_0)$  that leads to the best possible approximation

$$f(\mathbf{x}) \approx f(\mathbf{x}_0) + \langle \nabla f(\mathbf{x}_0), \mathbf{x} - \mathbf{x}_0 \rangle$$

Starting at  $\mathbf{x}_0$ , this term gets:

- bigger if we move in the direction of the gradient,
- smaller if we move in the opposite direction, and
- doesn't change if we move orthogonal to gradient.

# The gradient takes you uphill...

- Another way to think about it: direction of “steepest ascent”
- I.e., what direction should we travel to increase value of function as quickly as possible?
- This viewpoint leads to algorithms for optimization, commonly used in graphics.

# Gradient and Directional Derivative

At each point  $\mathbf{x}$ , gradient is unique vector  $\nabla f(\mathbf{x})$  such that

$$\langle \nabla f(\mathbf{x}), \mathbf{u} \rangle = D_{\mathbf{u}}f(\mathbf{x})$$

for all  $\mathbf{u}$ . In other words, such that taking the inner product w/ this vector gives you the directional derivative in any direction  $\mathbf{u}$ .

**Can't happen if function is not differentiable!**

**(Notice: gradient also depends on choice of *inner product*...)**

# Example: Gradient of Dot Product

- Consider the dot product expressed in terms of matrices:

$$f := \mathbf{u}^T \mathbf{v}$$

- What is gradient of  $f$  with respect to  $\mathbf{u}$ ?
- One way: write it out in coordinates:

$$\mathbf{u}^T \mathbf{v} = \sum_{i=1}^n u_i v_i$$

(equals zero unless  $i = k$ )

$$\frac{\partial}{\partial u_k} \sum_{i=1}^n u_i v_i = \sum_{i=1}^n \frac{\partial}{\partial u_k} (u_i v_i) = v_k$$

**In other words:**

$$\nabla_{\mathbf{u}} (\mathbf{u}^T \mathbf{v}) = \mathbf{v}$$

Not so different from  $\frac{d}{dx}(xy) = y!$

$$\Rightarrow \nabla_{\mathbf{u}} f = \begin{bmatrix} v_1 \\ \dots \\ v_n \end{bmatrix}$$

# Gradients of Matrix-Valued Expressions

- **EXTREMELY** useful in graphics to be able to differentiate expressions involving matrices
- Ultimately, expressions look much like ordinary derivatives

For any two vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$  and symmetric matrix  $\mathbf{A} \in \mathbb{R}^{n \times n}$ :

| MATRIX DERIVATIVE  | LOOKS LIKE                |
|--|---------------------------|
| $\nabla_{\mathbf{x}}(\mathbf{x}^T \mathbf{y}) = \mathbf{y}$                        | $\frac{d}{dx} xy = y$     |
| $\nabla_{\mathbf{x}}(\mathbf{x}^T \mathbf{x}) = 2\mathbf{x}$                       | $\frac{d}{dx} x^2 = 2x$   |
| $\nabla_{\mathbf{x}}(\mathbf{x}^T \mathbf{A} \mathbf{y}) = \mathbf{A} \mathbf{y}$  | $\frac{d}{dx} axy = ay$   |
| $\nabla_{\mathbf{x}}(\mathbf{x}^T \mathbf{A} \mathbf{x}) = 2\mathbf{A} \mathbf{x}$ | $\frac{d}{dx} ax^2 = 2ax$ |
| ...  | ...                       |

**Excellent resource: Petersen & Pedersen, "The Matrix Cookbook"**

- At least once in your life, work these out meticulously in coordinates (to convince yourself they're true).
- Then... forget about coordinates altogether!

# Advanced\*: L<sup>2</sup> Gradient

- Consider a function of a function  $F(f)$
- What is the gradient of  $F$  with respect to  $f$ ?
- Can't take partial derivatives anymore!
- Instead, look for function  $\nabla F$  such that for all functions  $u$ ,

$$\langle\langle \nabla F, u \rangle\rangle = D_u F$$

- What is *directional derivative of a function of a function*??
- Don't freak out—just return to good old-fashioned limit:

$$D_u F(f) = \lim_{\varepsilon \rightarrow 0} \frac{F(f + \varepsilon u) - F(f)}{\varepsilon}$$

- This strategy becomes much clearer w/ a concrete example...

\*as in, NOT on the test! (But perhaps somewhere in the test of life...)

# Advanced Visual Example: $L^2$ Gradient

- Consider function  $F(f) := \langle\langle f, g \rangle\rangle$  for  $f, g: [0,1] \rightarrow \mathbb{R}$
- I claim the gradient is:  $\nabla F = g$
- Does this make sense intuitively? How can we increase inner product with  $g$  as quickly as possible?
  - inner product measures how well functions are “aligned”
  - $g$  is definitely function best-aligned with  $g$ !
  - so to increase inner product, add a little bit of  $g$  to  $f$

# Advanced Example: $L^2$ Gradient

- Consider function  $F(f) := ||f||^2$  for arguments  $f: [0,1] \rightarrow \mathbb{R}$

- At each “point”  $f_0$ , we want function  $\nabla F$  such that for all functions  $u$

$$\langle\langle \nabla F(f_0), u \rangle\rangle = \lim_{\varepsilon \rightarrow 0} \frac{F(f_0 + \varepsilon u) - F(f_0)}{\varepsilon}$$

- Expanding 1st term in numerator, we get

$$||f_0 + \varepsilon u||^2 = ||f_0||^2 + \varepsilon^2 ||u||^2 + 2\varepsilon \langle\langle f_0, u \rangle\rangle$$

- Hence, limit becomes

$$\lim_{\varepsilon \rightarrow 0} (\varepsilon ||u||^2 + 2 \langle\langle f_0, u \rangle\rangle) = 2 \langle\langle f_0, u \rangle\rangle$$

- The only solution to  $\langle\langle \nabla F(f_0), u \rangle\rangle = 2 \langle\langle f_0, u \rangle\rangle$  for all  $u$  is

$$\boxed{\nabla F(f_0) = 2f_0}$$

← not much different from  $\frac{d}{dx} x^2 = 2x!$

## Key idea:

**Once you get the hang of taking the gradient of ordinary functions, it's (*superficially*) not much harder for more exotic objects like matrices, functions of functions, ...**

# Vector Fields

- Gradient was our first example of a **vector field**
- In general, a vector field assigns a vector to each point in space
- E.g., can think of a 2-vector field in the plane as a map

$$X : \mathbb{R}^2 \rightarrow \mathbb{R}^2$$

- For example, we saw a gradient field

$$\nabla f(x, y) = (2x, 2y)$$

(for the function  $f(x, y) = x^2 + y^2$ )

**Q: How do we measure the *change* in a  
vector field?**

# Divergence and Curl

- Two basic derivatives for vector fields:

“How much is field shrinking/expanding?”

“How much is field spinning?”

$\text{div } X$

$\text{curl } Y$

# Divergence

- Also commonly written as  $\nabla \cdot X$
- Suggests a coordinate definition for divergence
- Think of  $\nabla$  as a “vector of derivatives”

$$\nabla = \left( \frac{\partial}{\partial u_1}, \dots, \frac{\partial}{\partial u_n} \right)$$

- Think of  $X$  as a “vector of functions”

$$X(\mathbf{u}) = (X_1(\mathbf{u}), \dots, X_n(\mathbf{u}))$$

- Then divergence is

$$\nabla \cdot X := \sum_{i=1}^n \partial X_i / \partial u_i$$

$\nabla \cdot X$

# Divergence - Example

- Consider the vector field  $X(u, v) := (\cos(u), \sin(v))$
- Divergence is then

$$\nabla \cdot X = \frac{\partial}{\partial u} \cos(u) + \frac{\partial}{\partial v} \sin(v) = -\sin(u) + \cos(v).$$

$X$

$\nabla \cdot X$

# Curl

- Also commonly written as  $\nabla \times X$
- Suggests a coordinate definition for curl
- This time, think of  $\nabla$  as a vector of just *three* derivatives:

$$\nabla = \left( \frac{\partial}{\partial u_1}, \frac{\partial}{\partial u_2}, \frac{\partial}{\partial u_3} \right)$$

- Think of  $X$  as vector of *three* functions:

$$X(\mathbf{u}) = (X_1(\mathbf{u}), X_2(\mathbf{u}), X_3(\mathbf{u}))$$

- Then curl is

$$\nabla \times X := \begin{bmatrix} \partial X_3 / \partial u_2 - \partial X_2 / \partial u_3 \\ \partial X_1 / \partial u_3 - \partial X_3 / \partial u_1 \\ \partial X_2 / \partial u_1 - \partial X_1 / \partial u_2 \end{bmatrix}$$

**(2D "curl":**  $\nabla \times X := \partial X_2 / \partial u_1 - \partial X_1 / \partial u_2$ )  $\nabla \times X$

# Curl - Example

- Consider the vector field  $X(u, v) := (-\sin(v), \cos(u))$
- (2D) Curl is then

$$\nabla \times X = \frac{\partial}{\partial u} \cos(u) - \frac{\partial}{\partial v} (-\sin(v)) = -\sin(u) + \cos(v).$$

$X$

$\nabla \times X$

**Notice anything about the relationship  
between curl and divergence?**

# Divergence vs. Curl (2D)

- Divergence of  $X$  is the same as curl of 90-degree rotation of  $X$ :

$X$

$X^\perp$

$$\nabla \cdot X = \nabla \times X^\perp$$

- Playing these kinds of games w/ vector fields plays an important role in algorithms (e.g., fluid simulation)
- (Q: Can you come up with an analogous relationship in 3D?)

# Example: Fluids w/ Stream Function

$$\min_{\Psi} ||u^* - \nabla \times \Psi||^2$$

$$u = \nabla \times \Psi$$

$$\Delta p = \nabla \cdot u^*$$

$$u = u^* - \nabla p$$

# Laplacian

- One more operator we haven't seen yet: the **Laplacian**
- *Unbelievably* important object in graphics, showing up across geometry, rendering, simulation, imaging
  - basis for Fourier transform / frequency decomposition
  - used to define model PDEs (Laplace, heat, wave equations)
  - encodes rich information about geometry

# Laplacian—Visual Intuition

**Q: For ordinary function  $f(x)$ ,  
what does 2nd derivative tell us?**

**Likewise, Laplacian measures "curvature" of a function.**

For further interpretations of the Laplacian, see <https://youtu.be/oEq9R0l9Umk>

# Laplacian—Many Definitions

- Maps a scalar function to another scalar function (*linearly!*)

- Usually\* denoted by  $\Delta$  ← “Delta”

- *Many* starting points for Laplacian:

- divergence of gradient  $\Delta f := \nabla \cdot \nabla f = \text{div}(\text{grad } f)$

- sum of 2nd partial derivatives  $\Delta f := \sum_{i=1}^n \partial^2 f / \partial x_i^2$

- gradient of *Dirichlet energy*  $\Delta f := -\nabla_f \left( \frac{1}{2} \|\nabla f\|^2 \right)$

- by analogy: *graph Laplacian*

- variation of surface area

- trace of Hessian ...

|   |    |   |
|---|----|---|
|   | 1  |   |
| 1 | -4 | 1 |
|   | 1  |   |

$$\frac{4u_{ij} - u_{i+1,j} - u_{i-1,j} - u_{i,j+1} - u_{i,j-1}}{h^2} \quad \frac{1}{2} \sum_j (\cot \alpha_{ij} + \cot \beta_{ij})(u_j - u_i)$$

\*Or by  $\nabla^2$ , but we'll reserve this symbol for the *Hessian*

# Laplacian—Example

- Let's use coordinate definition:  $\Delta f := \sum_i \partial^2 f / \partial x_i^2$
- Consider the function  $f(x_1, x_2) := \cos(3x_1) + \sin(3x_2)$
- We have

$$\frac{\partial^2}{\partial x_1^2} f = \frac{\partial^2}{\partial x_1^2} \cos(3x_1) + \frac{\partial^2}{\partial x_1^2} \sin(3x_2) \overset{0}{=} -3 \frac{\partial}{\partial x_1} \sin(3x_1) = -9 \cos(3x_1).$$

and

$$\frac{\partial^2}{\partial x_2^2} f = -9 \sin(3x_2).$$

Hence,

$$\begin{aligned} \Delta f &= -9(\cos(3x_1) + \sin(3x_2)) \\ &= -9f \end{aligned}$$

← Interesting! Does this always happen?

$f$

$\Delta f$

# Hessian

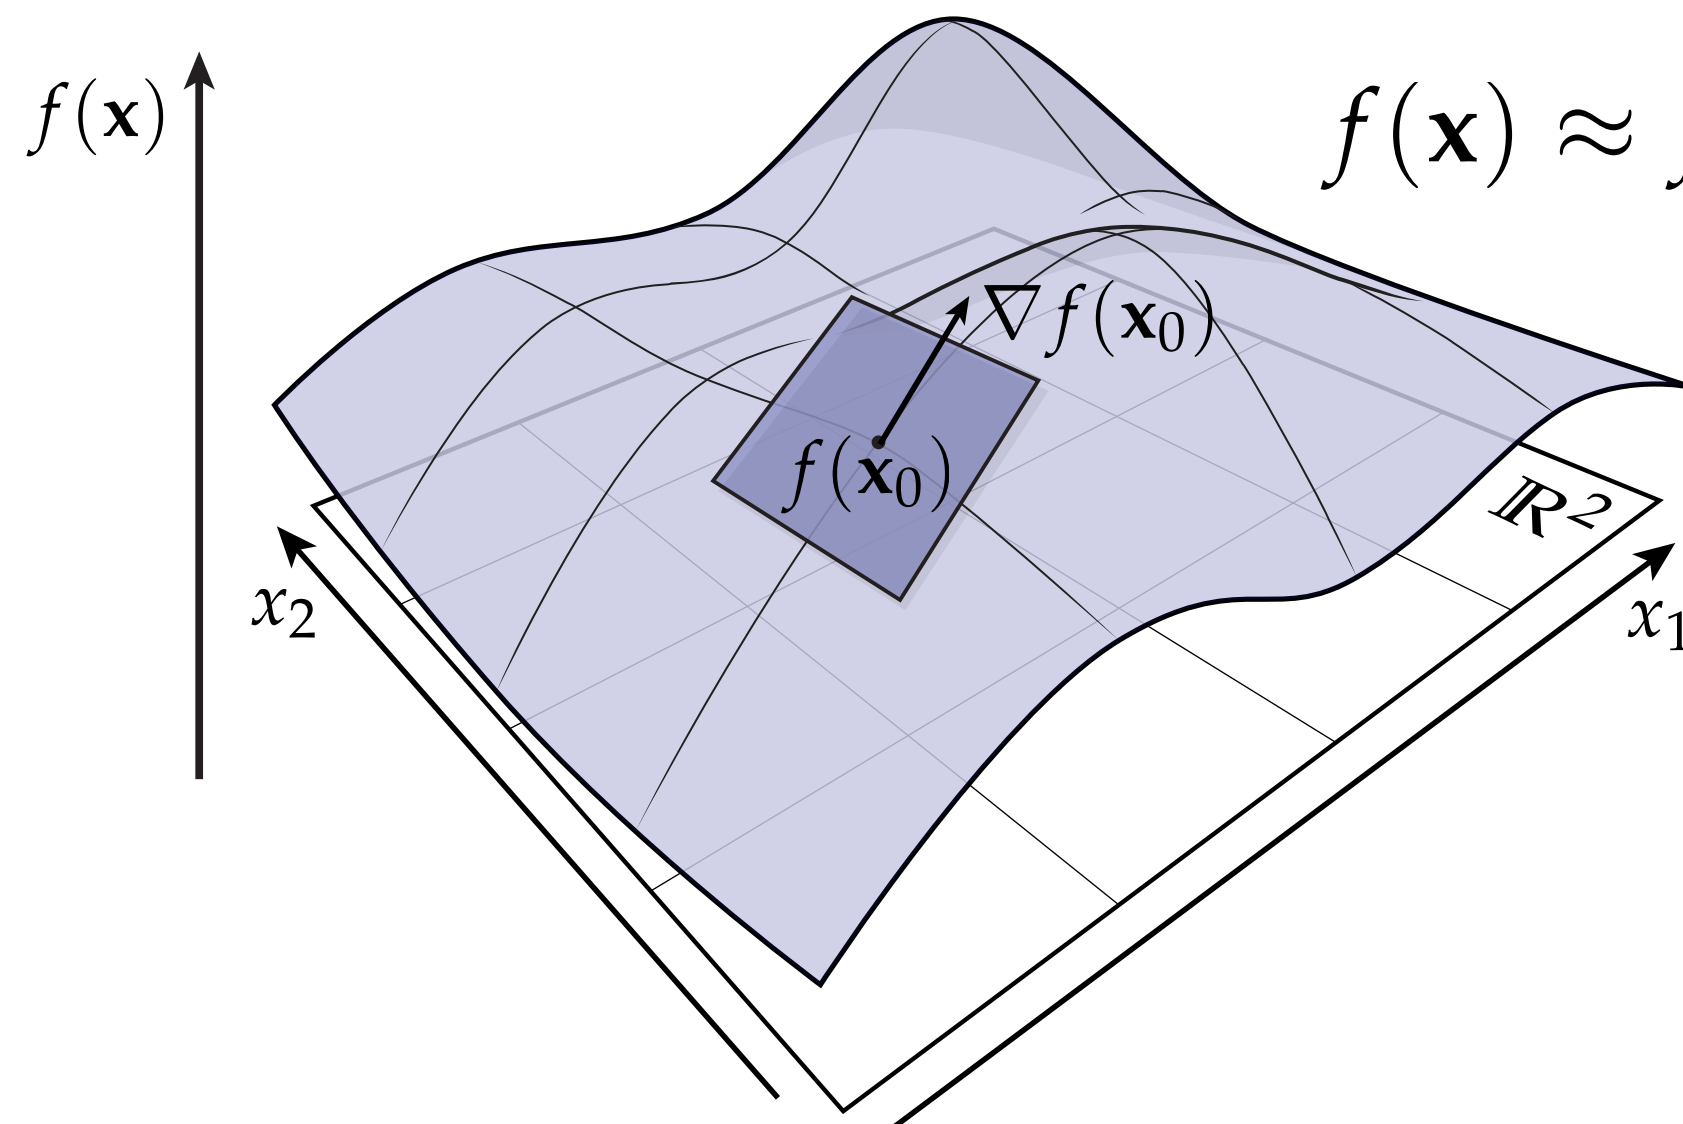

- Our final differential operator—**Hessian** will help us locally approximate complicated functions by a few simple terms

- Recall our *Taylor series*

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{(x-x_0)^2}{2!} f''(x_0) + \dots$$

- How do we do this for multivariable functions?

- Already talked about best *linear* approximation, using gradient:

$$f(\mathbf{x}) \approx f(\mathbf{x}_0) + \langle \nabla f(\mathbf{x}_0), \mathbf{x} - \mathbf{x}_0 \rangle$$

**Hessian gives us next,  
“quadratic” term.**

# Hessian in Coordinates

- Typically denote Hessian by symbol  $\nabla^2$
- Just as gradient was “vector that gives us partial derivatives of the *function*,” Hessian is “operator that gives us partial derivatives of the *gradient*”:

$$(\nabla^2 f) \mathbf{u} := D_{\mathbf{u}}(\nabla f)$$

- For a function  $f(\mathbf{x}): \mathbb{R}^n \rightarrow \mathbb{R}$ , can be more explicit:

$$\nabla^2 f := \begin{bmatrix} \frac{\partial^2 f}{\partial x_1 \partial x_1} & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_n \partial x_1} & \cdots & \frac{\partial^2 f}{\partial x_n \partial x_n} \end{bmatrix}$$

**Q: Why is this matrix always symmetric?**

# Taylor Series for Multivariable Functions

- Using Hessian, can now write 2nd-order approximation of any smooth, multivariable function  $f(\mathbf{x})$  around some point  $\mathbf{x}_0$ :

$$f(\mathbf{x}) \approx \underbrace{f(\mathbf{x}_0)}_{c \in \mathbb{R}} + \underbrace{\langle \nabla f(\mathbf{x}_0), \mathbf{x} - \mathbf{x}_0 \rangle}_{\mathbf{b} \in \mathbb{R}^n} + \underbrace{\langle \nabla^2 f(\mathbf{x}_0)(\mathbf{x} - \mathbf{x}_0), \mathbf{x} - \mathbf{x}_0 \rangle / 2}_{\mathbf{A} \in \mathbb{R}^{n \times n}}$$

- Can write this in matrix form as

$$f(\mathbf{u}) \approx \frac{1}{2} \mathbf{u}^T \mathbf{A} \mathbf{u} + \mathbf{b}^T \mathbf{u} + c, \quad \mathbf{u} := \mathbf{x} - \mathbf{x}_0$$

Will see later on how this approximation is *very* useful for optimization!

# Next time: Rasterization

- Next time, we'll talk about how to draw triangles
- A lot more interesting (and difficult!) than it might seem...
- Leads to a deep understanding of modern graphics hardware
