Motivation: The Rendering Equation

Recall the rendering equation, which models light "bouncing around the scene":

$$L_{o}(\mathbf{p},\omega_{o}) = L_{e}(\mathbf{p},\omega_{o}) + \int_{\mathcal{H}^{2}} f_{r}(\mathbf{p},\omega_{i} \to \omega_{o})$$

How can we possibly evaluate this integral?

quation odels light "bouncing

$L_i(\mathbf{p},\omega_i)\cos\theta\,d\omega_i$

Numerical Integration—Overview

- In graphics, many quantities we're interested in are naturally expressed as integrals (total brightness, total area, ...)
- For very, very simple integrals, we can compute the solution analytically
- For everything else, we have to compute a numerical approximation
- Basic idea:
 - integral is "area under curve"
 - sample the function at many points
 - integral is approximated as weighted sum

Rendering: what are we integrating? Recall this view of the world:

Want to "sum up"—i.e., integrate!—light from all directions (But let's start a little simpler...)

Review: integral as "area under curve"

Or: average value times size of domain

Review: fundamental theorem of calculus

 $\int_{a}^{b} f(x)dx = F(b) - F(a)$ $f(x) = \frac{d}{dx}F(x)$

F(x)

Simple case: constant function

Need only one sample of the function (at just the right place...)

More general polynomials?

Gauss Quadrature

For any polynomial of degree n, we can always obtain the exact integral by sampling at a special set of n points and taking a special weighted combination

Piecewise affine function

For piecewise functions, just sum integral of each piece:

Piecewise affine function

Key idea so far: To approximate an integral, we need quadrature points, and **(i)** (ii) weights for each point $\int_{a}^{b} f(x) \, dx \approx \sum_{i=1}^{n} w_i f(x_i)$

Arbitrary function f(x)?

Trapezoid rule <u>Approximate</u> integral of f(x) by assuming function is piecewise linear **For equal length segments:** $h = \frac{b-a}{m-1}$ f(x) $x_0 = a$ x_1 \mathcal{X}_2

Trapezoid rule

Consider cost and accuracy of estimate as $n \to \infty$ (or $h \to 0$) Work: O(n)

Error can be shown to be: $O(h^2) = O(\frac{1}{n^2})$

What about a 2D function?

How should we approximate the area underneath?

Integration in 2D **Consider integrating** f(x, y) using the trapezoidal rule (apply rule twice: when integrating in x and in y)

Errors add, so error still: $O(h^2)$ **But work is now:** $O(n^2)$ (n x n set of measurements)

In K-D, let

Error goes

Must perform much more work in 2D to get same error bound on integral!

$$N = n^k$$
as: $O\left(rac{1}{N^{2/k}}
ight)$

Curse of Dimensionality

- How much does it cost to apply the trapezoid rule as we go up in dimension?
 - 1D: O(n)
 - 2D: O(n²)

- **kD**: **O**(**n**^k)
- For many problems in graphics (like rendering), k is very, very big (e.g., tens or hundreds or thousands)
- Applying trapezoid rule does not scale!
- Need a fundamentally different approach...

Monte Carlo Integration

Credit: many of these slides were created by Matt Pharr and Pat Hanrahan

Monte Carlo Integration

- Estimate value of integral using random sampling of function
 - Value of estimate depends on random samples used
 - But algorithm gives the correct value of integral "on average"
- Only requires function to be evaluated at random points on its domain
 - Applicable to functions with discontinuities, functions that are impossible to integrate directly
 - **Error of estimate is independent of the dimensionality of the integrand**
 - Depends on the number of random samples used: $O(n^{1/2})$

(dropping the n² for simplicity)

So far we've discussed techniques that use a fixed set of sample points (e.g., uniformly spaced, or obtained by finding roots of polynomial (Gaussian quadrature))

Recall previous trapezoidal rule example: $O(n^{-1/k})$

Review: random variables

- random variable. Represents a distribution of Xpotential values
- $X \sim p(x)$ probability density function (PDF). Describes relative probability of a random process choosing value x
- **Uniform PDF: all values over a domain are equally likely**
- e.g., for an unbiased die X takes on values 1,2,3,4,5,6 p(1) = p(2) = p(3) = p(4) = p(5) = p(6)

Discrete probability distributions

n discrete values x_i

With probability p_i

Requirements of a PDF:

$$p_i \ge 0$$

$$\sum_{i=1}^{n} p_i = 1$$

Six-sided die example: $p_i = \frac{1}{6}$

Think: p_i is the probability that a random measurement of X will yield the value x_i X takes on the value x_i with probability p_i

Cumulative distribution function (CDF) (For a discrete probability distribution)

Cumulative PDF:
$$P_j = \sum_{i=1}^j p_i$$

where:

$$0 \leq P_i \leq 1$$

$$P_n = 1$$

 x_i

How do we generate samples of a discrete random variable (with a known PDF?)

Sampling from discrete probability distributions

To randomly select an event, select x_i if

$P_{i-1} < \xi \leq P_i$ **1 Uniform random variable** $\in [0, 1)$

2

Continuous probability distributions

PDF p(x) $p(x) \ge 0$ **CDF** P(x) $P(x) = \int_0^x p(x) \, \mathrm{d}x$ $P(x) = \Pr(X < x)$ P(1) = 1 $\Pr(a \le X \le b) = \int^b p(x) \, \mathrm{d}x$ Ja= P(b) - P(a)

Uniform distribution

(for random variable $X \operatorname{defined} \operatorname{on} \operatorname{[0,1]} \operatorname{domain})$

Sampling continuous random variables using the inversion method

Cumulative probability distribution function $P(x) = \Pr(X < x)$

Construction of samples: Solve for $x = P^{-1}(\xi)$

Must know the formula for:

- **1. The integral of** p(x)
- **2. The inverse function** $P^{-1}(x)$

Example—Sampling Quadratic Distribution

- As a toy example, consider the simple probability distribution p(x) := 3(x-1)² over the interval [0,1]
- How do we pick random samples distributed according to p(x)?
- First, integrate probability distribution p(x) to get cumulative distribution P(x)
- Invert P(x) by solving y = P(x) for x
- Finally, plug uniformly distributed random values y in [0,1] into this expression

 $p(x) := 3(x-1)^2$

$P(x) = x^3 - 3x^2 + 3x$

$\int_{0}^{0} 3(x-1)^{2} dx = s^{3} - 3s^{2} + 3s$

 $x = 1 - (1 - y)^{\frac{1}{3}}$

How do we uniformly sample the unit circle?

I.e., choose any point P=(px, py) in circle with equal probability)

Uniformly sampling unit circle: first try

- θ = uniform random angle between 0 and 2π
- r = uniform random radius between 0 and 1
- **Return point:** $(r \cos \theta, r \sin \theta)$

This algorithm <u>does not</u> produce the desired uniform sampling of the area of a circle. Why?

Because sampling is not uniform in area! Points farther from center of circle are less likely to be chosen

 $\theta = 2\pi\xi_1 \qquad r = \xi_2$

So how should we pick samples? Well, think about how we integrate over a disk in polar coordinates...

Sampling a circle (via inversion in 2D)

$$A = \int_0^{2\pi} \int_0^1 r \, \mathrm{d}r \, \mathrm{d}\theta = \int_0^1 r \, \mathrm{d}r \int_0^{2\pi} \mathrm{d}\theta$$

$$p(r,\theta) \,\mathrm{d}r \,\mathrm{d}\theta = \frac{1}{\pi} r \,\mathrm{d}r \,\mathrm{d}\theta \to p(r,\theta) = \frac{r}{\pi}$$

$$p(r, \theta) = p(r)p(\theta) \quad \label{eq:product}$$
 r, $heta$ independent

$$p(\theta) = \frac{1}{2\pi}$$

$$P(\theta) = \frac{1}{2\pi}\theta$$

$$p(r) = 2r$$

$$P(r) = r^2$$

 $\theta = 2\pi\xi_1$

Uniform area sampling of a circle

WRONG

probability is uniform; samples are not!

 $\theta = 2\pi \xi_1$

 $r = \xi_2$

RIGHT probability is nonuniform; samples are uniform

$$\theta = 2\pi\xi_1$$

$$r = \sqrt{\xi_2}$$

Uniform sampling via rejection sampling Completely different idea: pick uniform samples in square (easy) Then toss out any samples not in square (easy)

Efficiency of technique: area of circle / area of square

Efficiency of Rejection Sampling

If the region we care about covers only a very small fraction of the region we're sampling, rejection is probably a bad idea:

Smarter in this case to "warp" our random variables to follow the spiral.

Next Time: Monte Carlo Ray Tracing
